

第3章 行波法和 积分变换法

3.1 一维波动方程的达朗贝尔公式

3.4 积分变换法举例

3.1 一维波动方程的达朗贝尔公式

达朗贝尔 $D'Alembert$

常微分方程的初值问题：

先求出带有任意**常数**的通解，然后用初始条件确定**常数**得到定解。

类似地，

偏微分方程的初值问题：

先求出带有任意**函数**的通解，然后用初始条件确定**函数**得到定解。

引例

求定解问题

$$\begin{cases} u_{xy} = 6x^2y, & x > 1, y > 0 \\ u(x, 0) = x^2, u(1, y) = \cos y \end{cases}$$

- 两端同时对 x 积分 $\frac{\partial u}{\partial y} = 2x^3y + g_1(y)$
- 两端同时对 y 积分 $u(x, y) = x^3y^2 + g(y) + f(x)$

通解

$$u(x, y) = x^3 y^2 + g(y) + f(x)$$

$$\begin{cases} u(x, 0) = x^2 & \longrightarrow g(0) + f(x) = x^2 \\ u(1, y) = \cos y & \longrightarrow y^2 + g(y) + f(1) = \cos y \end{cases}$$

$$\begin{aligned} f(x) + g(y) &= x^2 + \cos y - y^2 - [g(0) + f(1)] \\ &= x^2 + \cos y - y^2 - 1 \end{aligned}$$

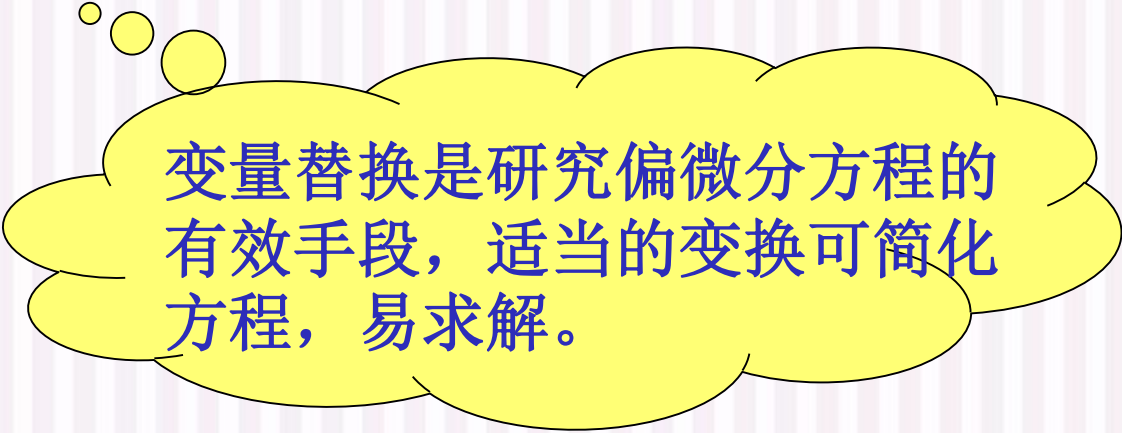

$$\therefore u(x, y) = x^3 y^2 + x^2 + \cos y - y^2 - 1$$

偏微分方程的初值问题：

先求出带有任意函数的通解，然后用初始条件确定函数得到定解。

关键步骤

通过(特征)变换，将偏微分方程化为便于积分的形式。

变量替换是研究偏微分方程的有效手段，适当的变换可简化方程，易求解。

Review: 二阶线性PDE的分类

$$Au_{xx} + 2Bu_{xy} + Cu_{yy} + Du_x + Eu_y + Fu = g(x, y) \quad (1)$$

令 $\Delta = B^2 - AC$, 若 $M(x_0, y_0) \in \Omega$ 使

(1) $\Delta(x_0, y_0) > 0$, 称方程在 M 点为**双曲型方程**;

如: 波动方程 $u_{tt} - a^2 u_{xx} = 0 \rightarrow \Delta = -(-a^2) > 0, a^2 = \frac{T}{\rho}$

(2) $\Delta(x_0, y_0) = 0$, 称方程在 M 点为**抛物线型方程**;

如: 热传导方程 $u_t - a^2 u_{xx} = 0 \rightarrow \Delta = 0, a^2 = \frac{k}{c\rho}$

(3) $\Delta(x_0, y_0) < 0$, 称方程在 M 点为**椭圆型方程**.

如: 拉普拉斯方程 $u_{xx} + u_{yy} = 0 \rightarrow \Delta = -1 < 0$

两个自变量的二阶线性PDE的化简

定理 设有可逆变换 $\begin{cases} \xi = \xi(x, y) \\ \eta = \eta(x, y) \end{cases}$ 使 $u(x, y) \rightarrow u(\xi, \eta)$,

其雅克比行列式满足 $J = \begin{vmatrix} \xi_x & \xi_y \\ \eta_x & \eta_y \end{vmatrix} \neq 0$ 则

- (1) $u(\xi, \eta)$ 与 $u(x, y)$ 有相同的方程类型;
- (2) 对三种类型方程, 各存在一组变换, 变为如下标准型:

双曲型: $u_{\xi\eta} = H_1(\xi, \eta, u, u_\xi, u_\eta)$

抛物线型: $u_{\eta\eta} = K(\xi, \eta, u, u_\xi, u_\eta)$

椭圆型: $u_{\xi\xi} = H_2(\xi, \eta, u, u_\xi, u_\eta)$

证明： 根据复合函数求导法则， 有

$$u \begin{cases} \xi \begin{cases} x \\ y \end{cases} \\ \eta \begin{cases} x \\ y \end{cases} \end{cases}$$

$$\left\{ \begin{array}{l} u_x = u_\xi \xi_x + u_\eta \eta_x \\ u_y = u_\xi \xi_y + u_\eta \eta_y \\ u_{xx} = (u_{\xi\xi} \xi_x^2 + u_{\xi\eta} \xi_x \eta_x + u_\xi \xi_{xx}) + (u_{\eta\xi} \eta_x \xi_x + u_{\eta\eta} \eta_x^2 + u_\eta \eta_{xx}) \\ \quad = u_{\xi\xi} \xi_x^2 + 2u_{\xi\eta} \xi_x \eta_x + u_{\eta\eta} \eta_x^2 + u_\xi \xi_{xx} + u_\eta \eta_{xx} \\ u_{xy} = u_{\xi\xi} \xi_x \xi_y + u_{\xi\eta} (\xi_x \eta_y + \xi_y \eta_x) + u_{\eta\eta} \eta_x \eta_y + u_\xi \xi_{xy} + u_\eta \eta_{xy} \\ u_{yy} = u_{\xi\xi} \xi_y^2 + 2u_{\xi\eta} \xi_y \eta_y + u_{\eta\eta} \eta_y^2 + u_\xi \xi_{yy} + u_\eta \eta_{yy} \end{array} \right.$$

—— 3.1 一维波动方程的达朗贝尔公式 ——

原: $Au_{xx} + 2Bu_{xy} + Cu_{yy} + Du_x + Eu_y + Fu = g(x, y)$

变换: $\xi = \xi(x, y), \eta = \eta(x, y)$

新: $\bar{A}u_{\xi\xi} + 2\bar{B}u_{\xi\eta} + \bar{C}u_{\eta\eta} + \bar{D}u_{\xi} + \bar{E}u_{\eta} + \bar{F}u = \bar{G}$

$$\bar{A} = A\xi_x^2 + 2B\xi_x\xi_y + C\xi_y^2$$

$$\bar{B} = A\xi_x\eta_x + B(\xi_x\eta_y + \xi_y\eta_x) + C\xi_y\eta_y$$

$$\bar{C} = A\eta_x^2 + 2B\eta_x\eta_y + C\eta_y^2$$

$$\bar{D} = A\xi_{xx} + 2B\xi_{xy} + C\xi_{yy} + D\xi_x + E\xi_y$$

$$\bar{E} = A\eta_{xx} + 2B\eta_{xy} + C\eta_{yy} + D\eta_x + E\eta_y$$

$$\bar{F} = F; \quad \bar{G} = g$$

若分别选取 ξ, η 为方程 $Az_x^2 + 2Bz_xz_y + Cz_y^2 = 0$ 的两个无关的解, 则

$$\bar{A} = 0, \quad \bar{C} = 0$$

方程可简化为:

$$u_{\xi\eta} = H_1(\xi, \eta, u, u_{\xi}, u_{\eta})$$

$$\bar{\Delta} = \bar{B}^2 - \bar{A}\bar{C} = J^2(B^2 - AC) = J^2\Delta \Rightarrow \text{变换前后有相同的方程类型.}$$

—— 3.1 一维波动方程的达朗贝尔公式 ——

$$Az_x^2 + 2Bz_xz_y + Cz_y^2 = 0 \Rightarrow A\left(-\frac{z_x}{z_y}\right)^2 - 2B\left(-\frac{z_x}{z_y}\right) + C = 0$$

由隐函数求导法则 $z(x, y) = 0 \Rightarrow \frac{dy}{dx} = -\frac{z_x}{z_y}$

一般形式的二阶线性偏微分方程

$$Au_{xx} + 2Bu_{xy} + Cu_{yy} + Du_x + Eu_y + Fu = g(x, y)$$

的特征方程为: $A\left(\frac{dy}{dx}\right)^2 - 2B\frac{dy}{dx} + C = 0$

$$\text{或 } A(dy)^2 - 2Bdx dy + C(dx)^2 = 0$$

特征方程 $A\left(\frac{dy}{dx}\right)^2 - 2B\frac{dy}{dx} + C = 0$ 的根为:

$$\frac{dy}{dx} = \begin{cases} \frac{B \pm \sqrt{B^2 - AC}}{A}, & B^2 - AC > 0 \\ \frac{B}{A}, & B^2 - AC = 0 \\ \frac{B \pm i\sqrt{AC - B^2}}{A}, & B^2 - AC < 0 \end{cases}$$

求解此一阶常微分方程，其解称为方程

$$Au_{xx} + 2Bu_{xy} + Cu_{yy} + Du_x + Eu_y + Fu = g(x, y) \quad (1)$$

的特征线.

第一种情况: $B^2 - AC > 0$

特征方程有两个实函数解

$$\frac{dy}{dx} = \frac{B \pm \sqrt{B^2 - AC}}{A}$$

此微分方程的解为 $\varphi(x, y) = C_1, \psi(x, y) = C_2$

方程(1)的两簇实特征线

取 $\xi = \varphi(x, y), \eta = \psi(x, y)$ 作变换, 则

$$\bar{A} = 0, \bar{C} = 0$$

方程可化为 $u_{\xi\eta} = H_1(\xi, \eta, u, u_\xi, u_\eta) \longrightarrow$

标准双曲
型方程

第二种情况: $B^2 - AC = 0$

特征方程有**重根** $\frac{dy}{dx} = \frac{B}{A}$, 此微分方程的解为

$\varphi(x, y) = C_0 \longrightarrow$ 特征线为一**簇实特征线**.

取 $\xi = \varphi(x, y)$, 则 $\bar{A} = 0$;

$$\bar{A} = A\xi_x^2 + 2B\xi_x\xi_y + C\xi_y^2 = (\sqrt{A}\xi_x + \sqrt{C}\xi_y)^2 = 0 \Rightarrow \sqrt{A}\xi_x + \sqrt{C}\xi_y = 0$$

$$\therefore \bar{B} = A\xi_x\eta_x + B(\xi_x\eta_y + \xi_y\eta_x) + C\xi_y\eta_y = (\sqrt{A}\xi_x + \sqrt{C}\xi_y)(\sqrt{A}\eta_x + \sqrt{C}\eta_y) = 0$$

所以可取 η 为任一与 ξ 独立的变换 $\psi(x, y)$, 则

方程可化为: $u_{\eta\eta} = K_1(\xi, \eta, u, u_\xi, u_\eta) \longrightarrow$

若取 $\eta = \varphi(x, y)$, 则方程可变换为

$$u_{\xi\xi} = K_2(\xi, \eta, u, u_\xi, u_\eta) \longrightarrow$$

线型
标准
方程
抛物

第三种情况: $B^2 - AC < 0$

特征方程有一对共轭复函数解

$$\frac{dy}{dx} = \frac{B \pm i\sqrt{AC - B^2}}{A}$$

方程的解为 $\varphi(x, y) = C_1, \psi(x, y) = \overline{\varphi(x, y)} = C_2$

→ 一对共轭复函数簇

取 $\xi = \varphi(x, y), \eta = \overline{\varphi(x, y)}$ 作变换, 则

$$\bar{A} = 0, \bar{C} = 0$$

方程可化为: $u_{\xi\eta} = H_2(\xi, \eta, u, u_\xi, u_\eta)$

标准椭圆
型方程

齐次一维波动方程的初值问题

- 研究对象

无界域波动方程 (波动方程初值问题)

- 求解方法

特征线法 (行波法)

弦振动方程的初值问题

——无界弦的振动

弦很长，考虑远离边界的某段弦在较短时间内的振动，其中给定初始位移和速度，并且没有强迫外力作用.

$$\begin{cases} \frac{\partial^2 u}{\partial t^2} = a^2 \frac{\partial^2 u}{\partial x^2}, & -\infty < x < +\infty, \quad t > 0 \\ \text{初始位移: } u(x, 0) = \varphi(x), \\ \text{初始速度: } u_t(x, 0) = \psi(x), & -\infty < x < +\infty \end{cases}$$

—— 3.1 一维波动方程的达朗贝尔公式 ——

$$\text{化简 } \frac{\partial^2 u}{\partial t^2} = a^2 \frac{\partial^2 u}{\partial x^2}$$

$$\text{特征方程 } \left(\frac{dx}{dt} \right)^2 - a^2 = 0 \Rightarrow \frac{dx}{dt} = \pm a \Rightarrow \text{特征线} \begin{cases} x + at = C_1 \\ x - at = C_2 \end{cases}$$

考虑代换 $\xi = x + at$, $\eta = x - at$

利用复合函数求导法则得

$$\frac{\partial u}{\partial x} = \frac{\partial u}{\partial \xi} \frac{\partial \xi}{\partial x} + \frac{\partial u}{\partial \eta} \frac{\partial \eta}{\partial x} = \frac{\partial u}{\partial \xi} + \frac{\partial u}{\partial \eta}$$

$$\frac{\partial^2 u}{\partial x^2} = \frac{\partial}{\partial \xi} \left(\frac{\partial u}{\partial \xi} + \frac{\partial u}{\partial \eta} \right) \frac{\partial \xi}{\partial x} + \frac{\partial}{\partial \eta} \left(\frac{\partial u}{\partial \xi} + \frac{\partial u}{\partial \eta} \right) \frac{\partial \eta}{\partial x} = \frac{\partial^2 u}{\partial \xi^2} + 2 \frac{\partial^2 u}{\partial \xi \partial \eta} + \frac{\partial^2 u}{\partial \eta^2}$$

$$\frac{\partial u}{\partial t} = a \frac{\partial u}{\partial \xi} - a \frac{\partial u}{\partial \eta}, \quad \frac{\partial^2 u}{\partial t^2} = a^2 \left(\frac{\partial^2 u}{\partial \xi^2} - 2 \frac{\partial^2 u}{\partial \xi \partial \eta} + \frac{\partial^2 u}{\partial \eta^2} \right)$$

代入方程, 得到 $\frac{\partial^2 u}{\partial \xi \partial \eta} = 0$

对 η 积分, 得 $\frac{\partial u}{\partial \xi} = f(\xi)$, $f(\xi)$ 是 ξ 的任意可微函数

$$\begin{aligned} \text{再对 } \xi \text{ 积分, 得 } u(x, t) &= \int f(\xi) d\xi + f_2(\eta) \\ &= f_1(x + at) + f_2(x - at) \end{aligned}$$

其中 f_1, f_2 都是任意二次连续可微函数.

利用初始条件，确定两个函数的具体形式.

$$u(x, t) = f_1(x + at) + f_2(x - at)$$

$$u|_{t=0} = \varphi(x) = f_1(x) + f_2(x) \quad \dots\dots\dots ①$$

$$u_t|_{t=0} = \psi(x) = af_1'(x) - af_2'(x) \quad \dots\dots\dots ②$$

$$\text{由②得} \int_{x_0}^x [af_1'(\xi) - af_2'(\xi)] d\xi = \int_{x_0}^x \psi(\xi) d\xi$$

$$[f_1(x) - f_1(x_0)] - [f_2(x) - f_2(x_0)] = \frac{1}{a} \int_{x_0}^x \psi(\xi) d\xi$$

$$\therefore f_1(x) - f_2(x) = \frac{1}{a} \int_{x_0}^x \psi(\xi) d\xi + C \quad \dots\dots\dots ③$$

$$\text{其中 } C = f_1(x_0) - f_2(x_0)$$

由①, ③得

$$f_1(x) = \frac{1}{2}\varphi(x) + \frac{1}{2a} \int_{x_0}^x \psi(\xi) d\xi + \frac{C}{2}$$

$$f_2(x) = \frac{1}{2}\varphi(x) - \frac{1}{2a} \int_{x_0}^x \psi(\xi) d\xi - \frac{C}{2}$$

代入通解表达式 $u(x, t) = f_1(x + at) + f_2(x - at)$

$$u(x, t) = \frac{1}{2} [\varphi(x + at) + \varphi(x - at)] + \frac{1}{2a} \int_{x-at}^{x+at} \psi(\xi) d\xi$$

— 达朗贝尔(D'Alembert)公式

达朗贝尔解的物理意义 $u(x, t) = f_1(x + at) + f_2(x - at)$

考虑 $u_2(x, t) = f_2(x - at)$

$t = 0$ 时, $u_2(x, 0) = f_2(x)$;

$t = t_1$ 时, $u_2(x, t_1) = f_2(x - at_1)$;

随着时间 t 的推移 u_2 的图形以速度 a 向 x 轴正方向行进, 称为**右行波**;

同理 $f_1(x + at)$ 表示一个以速度 a 向 x 轴负方向传播的行波, 称为**左行波**.

结论: 达朗贝尔解表示沿 x 轴正、反向传播的两列波速为 a 的波的叠加, 故称为行波法.

适用范围: 无界域内一维波动方程

$$\text{例1} \begin{cases} u_{tt} - a^2 u_{xx} = 0, & -\infty < x < \infty, t > 0 \\ u|_{t=0} = e^{-x^2}, & u_t|_{t=0} = 2axe^{-x^2}, -\infty < x < \infty \end{cases}$$

解：将初始条件代入达朗贝尔公式

$$\begin{aligned} u(x, t) &= \frac{1}{2} [e^{-(x+at)^2} + e^{-(x-at)^2}] + \frac{1}{2a} \int_{x-at}^{x+at} 2a\xi e^{-\xi^2} d\xi \\ &= \frac{1}{2} [e^{-(x+at)^2} + e^{-(x-at)^2}] + \frac{1}{2} \int_{x-at}^{x+at} e^{-\xi^2} d\xi^2 \\ &= e^{-(x-at)^2} \end{aligned}$$

$$u(x, t) = \frac{1}{2} [\varphi(x+at) + \varphi(x-at)] + \frac{1}{2a} \int_{x-at}^{x+at} \psi(\xi) d\xi$$

例2 设初始速度为零，初始位移为

$$\varphi(x) = \begin{cases} 1 + \frac{x}{a} & -a \leq x \leq 0 \\ 1 - \frac{x}{a} & 0 < x \leq a \\ 0 & x < -a \text{ 或 } x > a \end{cases}$$

求此条件下的无界域内一维波动方程的定解问题.

解：由达朗贝尔公式得问题的解为

$$u(x, t) = \frac{1}{2} \varphi(x + at) + \frac{1}{2} \varphi(x - at)$$

—— 3.1 一维波动方程的达朗贝尔公式 ——

红虚线: 左行波
蓝虚线: 右行波
黑实线: 弦的位移

行波法的说明:

$x + at = C_1, x - at = C_2 \rightarrow$ 一维波动方程的**特征线**

$$\xi = x + at, \eta = x - at \rightarrow \text{特征变换} \rightarrow \frac{\partial^2 u}{\partial \xi \partial \eta} = 0$$

行波法 $\rightarrow$ **特征线法**

可以证明, 当 $\Delta(x, y) = B^2 - AC > 0$ 时, 有两条相异的实特征线 $\varphi_1(x, y) = c_1, \varphi_2(x, y) = c_2$, 因此特征线法对双曲型方程都是有效的, 沿着特征线做自变量替换

$\xi = \varphi_1(x, y), \eta = \varphi_2(x, y)$, 总可以把齐次双曲型方程

化为 $\frac{\partial^2 u}{\partial \xi \partial \eta} = 0$, 从而得到方程的通解

$$u = f_1(\xi) + f_2(\eta)$$

例3 求下面问题的解:

$$\begin{cases} u_{xx} + 2u_{xy} - 3u_{yy} = 0, & -\infty < x < \infty, y > 0 \\ \text{初始条件: } u|_{y=0} = 3x^2, \quad u_y|_{y=0} = 0, & -\infty < x < \infty \end{cases}$$

解: 特征方程

$$\left(\frac{dy}{dx}\right)^2 - 2\frac{dy}{dx} - 3 = 0 \Rightarrow \frac{dy}{dx} = -1 \text{ 或 } \frac{dy}{dx} = 3$$

两族积分曲线为 $3x - y = C_1$ 和 $x + y = C_2$

做特征变换 $\xi = 3x - y, \quad \eta = x + y$

—— 3.1 一维波动方程的达朗贝尔公式 ——

$$\frac{\partial u}{\partial x} = 3 \frac{\partial u}{\partial \xi} + \frac{\partial u}{\partial \eta}, \quad \frac{\partial^2 u}{\partial x^2} = 9 \frac{\partial^2 u}{\partial \xi^2} + 6 \frac{\partial^2 u}{\partial \xi \partial \eta} + \frac{\partial^2 u}{\partial \eta^2}$$

$$\frac{\partial^2 u}{\partial x \partial y} = -3 \frac{\partial^2 u}{\partial \xi^2} + 2 \frac{\partial^2 u}{\partial \xi \partial \eta} + \frac{\partial^2 u}{\partial \eta^2},$$

$$\frac{\partial u}{\partial y} = -\frac{\partial u}{\partial \xi} + \frac{\partial u}{\partial \eta}, \quad \frac{\partial^2 u}{\partial y^2} = \frac{\partial^2 u}{\partial \xi^2} - 2 \frac{\partial^2 u}{\partial \xi \partial \eta} + \frac{\partial^2 u}{\partial \eta^2}$$

代入方程化简得: $\frac{\partial^2 u}{\partial \xi \partial \eta} = 0$

于是原方程的通解为

$$u(x, y) = f_1(3x - y) + f_2(x + y)$$

代入初始条件 $u|_{y=0} = 3x^2$, $u_y|_{y=0} = 0$ 得

$$f_1(3x) + f_2(x) = 3x^2$$

$$-f_1'(3x) + f_2'(x) = 0 \rightarrow -\frac{1}{3}f_1(3x) + f_2(x) = C$$

$$f_1(3x) = \frac{9}{4}x^2 - \frac{3}{4}C \Rightarrow f_1(x) = \frac{1}{4}x^2 - \frac{3}{4}C$$

$$f_2(x) = \frac{3}{4}x^2 + \frac{3}{4}C$$

所求问题的解为

$$\begin{aligned} u(x, y) &= f_1(3x - y) + f_2(x + y) \\ &= \frac{1}{4}(3x - y)^2 + \frac{3}{4}(x + y)^2 = 3x^2 + y^2 \end{aligned}$$

3.4 积分变换法

- 傅里叶变换:

(1) Fourier 正变换(简称傅氏正变换)

$$F(\omega) = \int_{-\infty}^{+\infty} f(t) e^{-j\omega t} dt = \mathcal{F}[f(t)]$$

(2) Fourier 逆变换(简称傅氏逆变换)

$$f(t) = \frac{1}{2\pi} \int_{-\infty}^{+\infty} F(\omega) e^{j\omega t} d\omega = \mathcal{F}^{-1}[F(\omega)]$$

其中, $F(\omega)$ 称为像函数, $f(t)$ 称为像原函数.

$f(t)$ 与 $F(\omega)$ 称为傅氏变换对, 记为 $f(t) \leftrightarrow F(\omega)$.

- 卷积

$$f_1(t) * f_2(t) = \int_{-\infty}^{+\infty} f_1(\tau) f_2(t - \tau) d\tau.$$

卷积由反褶、平移、相乘、积分四个部分组成

积分变换法解偏微分方程的基本思想

利用傅立叶变换或拉普拉斯变换，通过对方程（及定解条件）中某一个变量取积分变换后，使自变量减少一个，得到含有一个参量的常微分方程。求解后，再通过逆变换，得到原解。

$$\begin{array}{ccc} u(x, t) & \xrightarrow{\text{傅氏正变换}} & U(x, \omega) \rightarrow U(x, \omega) \text{ 的常微分方程} \\ & & \text{(参变量 } \omega \text{ 看成常量)} \quad \Downarrow \\ & & u(x, t) \xleftarrow{\text{傅氏逆变换}} \text{解出 } U(x, \omega) \end{array}$$

如何使用积分变换法求解定解问题：

- 1) 选取恰当的积分变换，对某个自变量作积分变换，得到象函数的含参变量 ω 常微分方程；
傅立叶变换变量取值范围： $(-\infty, +\infty)$
- 2) 对部分定解条件取相应的积分变换，导出象函数方程的定解条件；
- 3) 解关于象函数的定解问题，求出象函数；
- 4) 将象函数取积分逆变换，即得原定解问题的解。

常用工具:

傅里叶变换
微分性质

$$\mathcal{F}[f^{(n)}(t)] = (j\omega)^n F(\omega);$$

$$\mathcal{F}^{-1}[F^{(n)}(\omega)] = (-jt)^n f(t).$$

傅里叶变换
位移性质

设 t_0, ω_0 为实常数, 则

$$(1) \mathcal{F}[f(t - t_0)] = e^{-j\omega t_0} F(\omega); \quad (\text{时移性质})$$

$$(2) \mathcal{F}^{-1}[F(\omega - \omega_0)] = e^{j\omega_0 t} f(t). \quad (\text{频移性质})$$

卷积定理

$$\mathcal{F}[f_1(t) * f_2(t)] = F_1(\omega) \cdot F_2(\omega);$$

$$\mathcal{F}^{-1}[F_1(\omega) * F_2(\omega)] = 2\pi f_1(t) \cdot f_2(t).$$

例1 用积分变换法解方程

$$\begin{cases} \frac{\partial u}{\partial t} = \frac{\partial^2 u}{\partial x^2}, & -\infty < x < +\infty, t > 0 \\ u(x, 0) = \varphi(x), & -\infty < x < +\infty \end{cases}$$

- 因为 t 的范围是 $(0, +\infty)$, 因此不能对 t 做傅里叶变换
- 应该对 x 做傅里叶变换 (因其变量范围是 $(-\infty, +\infty)$)

解: 方程和初值条件做关于 x 的傅里叶变换, 设

$$u(x, t) \rightarrow U(\omega, t) = \int_{-\infty}^{+\infty} u(x, t) e^{-i\omega x} dx$$

$$\varphi(x) \rightarrow \Phi(\omega) = \int_{-\infty}^{+\infty} \varphi(x) e^{-i\omega x} dx$$

$$\mathcal{F}[f^{(n)}(x)] = (j\omega)^n F(\omega)$$

方程两端对 x 做傅氏变换, t 不动, 且使用微分性质

$$\begin{cases} \frac{dU(\omega, t)}{dt} = (i\omega)^2 U(\omega, t) = -\omega^2 U(\omega, t) \\ U(\omega, 0) = \Phi(\omega) \end{cases}$$

$U(\omega, t)$ 是 t 的函数,
参变量 ω 看成常量

$$\begin{cases} \frac{dU(\omega, t)}{dt} = -\omega^2 U(\omega, t) \\ U(\omega, 0) = \Phi(\omega) \end{cases} \quad \text{关于 } t \text{ 的一阶常微分方程}$$

$$\Rightarrow U(\omega, t) = Ce^{-\omega^2 t}$$

一阶齐次线性微分方程

$$y' + P(x)y = 0$$

的通解为 $y = Ce^{-\int P(x)dx}$

代入初值条件

$$U(\omega, 0) = Ce^{-\omega^2 \cdot 0} = \Phi(\omega) \Rightarrow C = \Phi(\omega)$$

$$\text{因此 } U(\omega, t) = Ce^{-\omega^2 t} = \Phi(\omega)e^{-\omega^2 t}$$

$$\begin{aligned} \text{做傅里叶逆变换 } u(x, t) &= \mathcal{F}^{-1}[U(\omega, t)] \\ &= \mathcal{F}^{-1}[\Phi(\omega)e^{-\omega^2 t}] = \varphi(x) * \mathcal{F}^{-1}(e^{-\omega^2 t}) \end{aligned}$$

$$u(x, t) = \mathcal{F}^{-1} [U(\omega, t)] = \varphi(x) * \mathcal{F}^{-1} (e^{-\omega^2 t})$$

根据已知傅里叶变换对（考试时会给出常用变换对）

$$\frac{1}{\sqrt{2\pi}\sigma} e^{\frac{-x^2}{2\sigma^2}} \leftrightarrow e^{\frac{-\omega^2 \sigma^2}{2}}$$

$$\text{得到 } \mathcal{F}^{-1} (e^{-\omega^2 t}) = \frac{1}{2\sqrt{\pi t}} e^{\frac{-x^2}{4t}}$$

$$u(x, t) = \varphi(x) * \frac{1}{2\sqrt{\pi t}} e^{\frac{-x^2}{4t}} = \frac{1}{2\sqrt{\pi t}} \int_{-\infty}^{+\infty} \varphi(x - \tau) e^{\frac{-\tau^2}{4t}} d\tau$$

注意本题一直是在对x做变换，卷积也是认为是针对自变量x在卷积，要判断清楚！

例2 用积分变换法解方程

$$\begin{cases} u_{tt} = a^2 u_{xx} & (-\infty < x < +\infty, t > 0) \\ u|_{t=0} = \varphi(x), \quad u_t|_{t=0} = \psi(x) \end{cases}$$

解：方程和初值条件做关于 x 的傅里叶变换，设

$$u(x, t) \leftrightarrow U(\omega, t), \quad \varphi(x) \leftrightarrow \Phi(\omega), \quad \psi(x) \leftrightarrow \Psi(\omega)$$

原方程可以变为：

$$\begin{cases} \frac{d^2 U(\omega, t)}{dt^2} = (i\omega)^2 a^2 U(\omega, t) = -a^2 \omega^2 U(\omega, t) \\ U(\omega, 0) = \Phi(\omega), \quad \frac{dU(\omega, 0)}{dt} = \Psi(\omega) \end{cases}$$

$$\begin{cases} \frac{d^2 U(\omega, t)}{dt^2} = (i\omega)^2 a^2 U(\omega, t) = -a^2 \omega^2 U(\omega, t) \\ U(\omega, 0) = \Phi(\omega), \frac{dU(\omega, 0)}{dt} = \Psi(\omega) \end{cases}$$

方程的通解为 $U(\omega, t) = C_1 \cos(a\omega t) + C_2 \sin(a\omega t)$

根据初值条件 $U(\omega, 0) = C_1 \cos(a\omega 0) + C_2 \sin(a\omega 0) = \Phi(\omega)$

$$\frac{dU(\omega, 0)}{dt} = -a\omega C_1 \sin(a\omega 0) + a\omega C_2 \cos(a\omega 0) = \Psi(\omega)$$

$$\text{解得 } C_1 = \Phi(\omega), C_2 = \frac{\Psi(\omega)}{a\omega}$$

$$\therefore U(\omega, t) = \Phi(\omega) \cos(a\omega t) + \frac{\Psi(\omega)}{a\omega} \sin(a\omega t)$$

—— 3.4 积分变换法 ——

$$U(\omega, t) = \Phi(\omega)\cos(a\omega t) + \frac{\Psi(\omega)}{a\omega}\sin(a\omega t)$$

做傅里叶逆变换

$$\begin{aligned} u(x, t) &= \mathcal{F}^{-1}[U(\omega, t)] \\ &= \mathcal{F}^{-1}[\Phi(\omega)\cos(a\omega t)] + \mathcal{F}^{-1}\left[\frac{\Psi(\omega)}{a\omega}\sin(a\omega t)\right] \end{aligned}$$

其中

$$\begin{aligned} \mathcal{F}^{-1}[\Phi(\omega)\cos(a\omega t)] &= \mathcal{F}^{-1}\left[\Phi(\omega)\frac{e^{ia\omega t} + e^{-ia\omega t}}{2}\right] \\ &= \frac{\varphi(x + at) + \varphi(x - at)}{2} \end{aligned}$$

$$\mathcal{F}[f(t - t_0)] = e^{-j\omega t_0} F(\omega); \quad (\text{时移性质})$$

$$\text{另外 } \mathcal{F}^{-1} \left[\frac{\Psi(\omega)}{a\omega} \sin(a\omega t) \right] = \mathcal{F}^{-1} \left[\frac{\Psi(\omega)}{2a} \frac{e^{ia\omega t} - e^{-ia\omega t}}{i\omega} \right]$$

$$= \frac{1}{2a} \cdot \frac{1}{2\pi} \int_{-\infty}^{+\infty} \left[\Psi(\omega) \left(e^{-ix\omega} \int_{x-at}^{x+at} e^{i\xi\omega} d\xi \right) \right] e^{ix\omega} d\omega$$

$$\text{利用 } \int_{x-at}^{x+at} e^{i\xi\omega} d\xi = \frac{e^{i(x+at)\omega} - e^{i(x-at)\omega}}{i\omega} = e^{ix\omega} \cdot \frac{e^{ia\omega t} - e^{-ia\omega t}}{i\omega}$$

$$\mathcal{F}^{-1} \left[\frac{\Psi(\omega)}{a\omega} \sin(a\omega t) \right] = \frac{1}{2a} \cdot \int_{x-at}^{x+at} \left[\frac{1}{2\pi} \left(\int_{-\infty}^{+\infty} \Psi(\omega) e^{i\xi\omega} d\omega \right) \right] d\xi$$

$$= \frac{1}{2a} \int_{x-at}^{x+at} \psi(\xi) d\xi$$

D'Alembert (达朗贝尔) 公式

$$\therefore u(x, t) = \frac{1}{2} [\varphi(x + at) + \varphi(x - at)] + \frac{1}{2a} \int_{x-at}^{x+at} \psi(\xi) d\xi$$

例3 用积分变换法解方程

$$\begin{cases} u_{tt} = a^2 u_{xx} + f(x, t) & (-\infty < x < +\infty, t > 0) \\ u|_{t=0} = 0, \quad u_t|_{t=0} = 0 \end{cases}$$

解：方程做关于x的傅里叶变换，设

$$u(x, t) \leftrightarrow U(\omega, t), \quad f(x, t) \leftrightarrow G(\omega, t)$$

原方程可以变为：

$$\begin{cases} \frac{d^2 U(\omega, t)}{dt^2} + a^2 \omega^2 U(\omega, t) = G(\omega, t) \\ U(\omega, 0) = 0, \quad \frac{dU(\omega, 0)}{dt} = 0 \end{cases}$$

—— 3.4 积分变换法 ——

$$\begin{cases} \frac{d^2 U(\omega, t)}{dt^2} + a^2 \omega^2 U(\omega, t) = G(\omega, t) \\ U(\omega, 0) = 0, \frac{dU(\omega, 0)}{dt} = 0 \end{cases}$$

常数变易法

$$\begin{aligned} & y'' + w^2 y = f(x) \text{ 的解} \\ & \frac{1}{w} \int_0^x f(t) \sin w(x-t) dt \\ & \text{满足 } y(0) = 0, y'(0) = 0 \end{aligned}$$

$$U(\omega, t) = \frac{1}{a\omega} \int_0^t G(\omega, \tau) \sin a\omega(t-\tau) d\tau$$

特别注意变量的对应关系！别搞错！

$$U(\omega, t) = \frac{1}{a\omega} \int_0^t G(\omega, \tau) \sin a\omega(t - \tau) d\tau$$

做傅里叶逆变换

$$u(x, t) = \mathcal{F}^{-1}[U(\omega, t)] = \mathcal{F}^{-1}\left[\frac{1}{a\omega} \int_0^t G(\omega, \tau) \sin a\omega(t - \tau) d\tau\right]$$

根据已知傅里叶变换对

$$f(t) = \begin{cases} h, & -\tau < t < \tau \\ 0, & \text{其它} \end{cases} \leftrightarrow 2h \frac{\sin \omega\tau}{\omega}$$

$$\mathcal{F}^{-1}\left[\frac{\sin a\omega(t - \tau)}{\omega}\right] = p(x) = \begin{cases} \frac{1}{2}, & -a(t - \tau) < x < a(t - \tau) \\ 0, & \text{其它} \end{cases}$$

$$u(x, t) = \mathcal{F}^{-1} [U(\omega, t)] = \mathcal{F}^{-1} \left[\frac{1}{a\omega} \int_0^t G(\omega, \tau) \sin a\omega(t - \tau) d\tau \right]$$

$$\mathcal{F}^{-1} \left[\frac{\sin a\omega(t - \tau)}{\omega} \right] = p(x) = \begin{cases} \frac{1}{2}, & -a(t - \tau) < x < a(t - \tau) \\ 0, & \text{其它} \end{cases}$$

$$u(x, t) = \mathcal{F}^{-1} [U(\omega, t)] = \frac{1}{a} \int_0^t \mathcal{F}^{-1} \left[G(\omega, \tau) \frac{\sin a\omega(t - \tau)}{\omega} \right] d\tau$$

利用卷
积性质

$$= \frac{1}{a} \int_0^t f(x, \tau) * p(x) d\tau = \frac{1}{a} \int_0^t \int_{-\infty}^{+\infty} f(y, \tau) p(x - y) dy d\tau$$

$$= \frac{1}{2a} \int_0^t \int_{x-a(t-\tau)}^{x+a(t-\tau)} f(y, \tau) dy d\tau$$

例4 解方程

$$\begin{cases} u_{tt} = a^2 u_{xx} + f(x, t) & (-\infty < x < +\infty, t > 0) \\ u|_{t=0} = \varphi(x), \quad u_t|_{t=0} = \psi(x) \end{cases}$$

$$\begin{array}{ll} \text{例2} \begin{cases} u_{tt} = a^2 u_{xx} \\ u|_{t=0} = \varphi(x), \quad u_t|_{t=0} = \psi(x) \end{cases} & \text{例3} \begin{cases} u_{tt} = a^2 u_{xx} + f(x, t) \\ u|_{t=0} = 0, \quad u_t|_{t=0} = 0 \end{cases} \end{array}$$

叠加例2和例3的解，得：

$$\begin{aligned} u(x, t) = & \frac{1}{2} [\varphi(x + at) + \varphi(x - at)] + \frac{1}{2a} \int_{x-at}^{x+at} \psi(\xi) d\xi \\ & + \frac{1}{2a} \int_0^t \int_{x-a(t-\tau)}^{x+a(t-\tau)} f(y, \tau) dy d\tau \end{aligned}$$
